

Capital Stock Utilization Delta and the Cross Section of Stock Returns

I. M. Harking

December 1, 2024

Abstract

This paper studies the asset pricing implications of Capital Stock Utilization Delta (CSUD), and its robustness in predicting returns in the cross-section of equities using the protocol proposed by [Novy-Marx and Velikov \(2023\)](#). A value-weighted long/short trading strategy based on CSUD achieves an annualized gross (net) Sharpe ratio of 0.51 (0.45), and monthly average abnormal gross (net) return relative to the [Fama and French \(2015\)](#) five-factor model plus a momentum factor of 19 (19) bps/month with a t-statistic of 2.37 (2.39), respectively. Its gross monthly alpha relative to these six factors plus the six most closely related strategies from the factor zoo (Share issuance (1 year), Net Payout Yield, Growth in book equity, Change in equity to assets, Share issuance (5 year), Asset growth) is 15 bps/month with a t-statistic of 1.99.

1 Introduction

The efficient market hypothesis suggests that asset prices should fully reflect all available information. However, a growing body of literature documents numerous market anomalies that challenge this fundamental premise. While many of these anomalies are well-documented, the role of firms’ operational decisions in driving asset prices remains incompletely understood.

One particularly understudied aspect is how changes in capital stock utilization affect stock returns. While research has extensively examined capital investment decisions [Titman et al. \(2004\)](#) and capacity utilization levels [Cooper et al. \(2021\)](#), the dynamic adjustments in how firms utilize their existing capital stock have received limited attention in the asset pricing literature.

We propose that changes in capital stock utilization (CSUD) contain valuable information about future stock returns through several economic channels. First, following [Belo et al. \(2014\)](#), firms’ optimal production decisions reflect their expectations of future demand and profitability. When managers anticipate stronger future performance, they are likely to increase the utilization of existing capital stock before making new capital investments, making CSUD an early signal of future prospects.

Second, building on real options theory [Dixit and Pindyck \(1994\)](#), changes in capital utilization represent a relatively low-cost way to adjust output compared to irreversible capital investments. The flexibility to adjust utilization creates option value that should be reflected in stock prices. Higher CSUD may indicate that firms are exercising these real options optimally in response to positive information.

Third, consistent with [Zhang \(2005\)](#), capital adjustment costs make it costly for firms to quickly alter their capital stock. In this framework, CSUD serves as an important margin of adjustment that helps firms optimize operations before undertaking more expensive capital investments. The information content in these utilization changes may not be fully and immediately incorporated into stock prices

due to investor inattention [Hirshleifer and Teoh \(2003\)](#).

Our empirical analysis reveals that CSUD strongly predicts future stock returns. A value-weighted long-short portfolio strategy that buys stocks with high CSUD and sells stocks with low CSUD generates significant abnormal returns of 19 basis points per month (t-statistic = 2.37) relative to the Fama-French five-factor model plus momentum. The strategy achieves an annualized gross Sharpe ratio of 0.51, placing it in the top decile of documented market anomalies.

Importantly, the predictive power of CSUD remains robust after controlling for size. Among the largest quintile of stocks, the CSUD strategy earns abnormal returns of 27 basis points per month (t-statistic = 2.80). This finding suggests that the CSUD effect is not merely a small-stock phenomenon and could be implemented by institutional investors.

The economic significance of CSUD persists even after accounting for transaction costs and controlling for related anomalies. The strategy’s net Sharpe ratio of 0.45 ranks in the 99th percentile across 212 documented anomalies. Controlling for the six most closely related anomalies and the Fama-French six factors simultaneously, CSUD continues to generate an alpha of 15 basis points per month (t-statistic = 1.99).

Our paper makes several contributions to the asset pricing literature. First, we introduce a novel return predictor based on firms’ operational decisions that captures information not fully reflected in traditional accounting and market-based signals. While prior work has examined capital investment [Titman et al. \(2004\)](#) and capacity utilization levels [Cooper et al. \(2021\)](#), we show that changes in utilization provide distinct predictive content.

Second, we extend the literature on real options and asset prices [Belo et al. \(2014\)](#) by demonstrating how firms’ flexible adjustment of capital utilization reveals information about future prospects. Our findings suggest that the market does not

fully appreciate the signaling value of these operational decisions, consistent with models of limited investor attention [Hirshleifer and Teoh \(2003\)](#).

Third, we contribute to the growing literature on factor investing by documenting a robust new predictor that maintains its effectiveness among large, liquid stocks and after controlling for transaction costs. The exceptional performance of CSUD relative to the factor zoo [Chen and Zimmermann \(2022\)](#) suggests it captures a distinct dimension of expected returns with meaningful economic content.

2 Data

Our study investigates the predictive power of a financial signal derived from accounting data for cross-sectional returns, focusing specifically on Capital Stock Utilization Delta. We obtain accounting and financial data from COMPUSTAT, covering firm-level observations for publicly traded companies. To construct our signal, we use COMPUSTAT’s item CSTK for capital stock and item CAPXV for capital expenditure. Capital stock (CSTK) represents the firm’s total capital assets, including property, plant, and equipment, while capital expenditure (CAPXV) reflects the firm’s investment in long-term assets during the fiscal year. The construction of the signal follows a difference-based approach, where we first calculate the year-over-year change in CSTK (CSTK minus lagged CSTK) and then scale this difference by the previous year’s capital expenditure (lagged CAPXV). This scaled difference captures the relative change in a firm’s capital stock relative to its recent investment activity, providing insight into how effectively the firm is utilizing and managing its capital resources. By focusing on this relationship, the signal aims to reflect aspects of capital efficiency and investment productivity in a manner that is both scalable and interpretable. We construct this measure using end-of-fiscal-year values for both CSTK and CAPXV to ensure consistency and comparability across firms and over

time.

3 Signal diagnostics

Figure 1 plots descriptive statistics for the CSUD signal. Panel A plots the time-series of the mean, median, and interquartile range for CSUD. On average, the cross-sectional mean (median) CSUD is -0.45 (-0.00) over the 1966 to 2023 sample, where the starting date is determined by the availability of the input CSUD data. The signal’s interquartile range spans -0.09 to 0.00. Panel B of Figure 1 plots the time-series of the coverage of the CSUD signal for the CRSP universe. On average, the CSUD signal is available for 5.87% of CRSP names, which on average make up 7.32% of total market capitalization.

4 Does CSUD predict returns?

Table 1 reports the performance of portfolios constructed using a value-weighted, quintile sort on CSUD using NYSE breaks. The first two lines of Panel A report monthly average excess returns for each of the five portfolios and for the long/short portfolio that buys the high CSUD portfolio and sells the low CSUD portfolio. The rest of Panel A reports the portfolios’ monthly abnormal returns relative to the five most common factor models: the CAPM, the Fama and French (1993) three-factor model (FF3) and its variation that adds momentum (FF4), the Fama and French (2015) five-factor model (FF5), and its variation that adds momentum factor used in Fama and French (2018) (FF6). The table shows that the long/short CSUD strategy earns an average return of 0.31% per month with a t-statistic of 3.87. The annualized Sharpe ratio of the strategy is 0.51. The alphas range from 0.19% to 0.34% per month and have t-statistics exceeding 2.37 everywhere. The lowest alpha is with respect to the FF6 factor model.

Panel B reports the six portfolios’ loadings on the factors in the [Fama and French \(2018\)](#) six-factor model. The long/short strategy’s most significant loading is 0.34, with a t-statistic of 6.36 on the CMA factor. Panel C reports the average number of stocks in each portfolio, as well as the average market capitalization (in \$ millions) of the stocks they hold. In an average month, the five portfolios have at least 526 stocks and an average market capitalization of at least \$1,348 million.

Table 2 reports robustness results for alternative sorting methodologies, and accounting for transaction costs. These results are important, because many anomalies are far stronger among small cap stocks, but these small stocks are more expensive to trade. Construction methods, or even signal-size correlations, that over-weight small stocks can yield stronger paper performance without improving an investor’s achievable investment opportunity set. Panel A reports gross returns and alphas for the long/short strategies made using various different portfolio constructions. The first row reports the average returns and the alphas for the long/short strategy from Table 1, which is constructed from a quintile sort using NYSE breakpoints and value-weighted portfolios. The rest of the panel shows the equal-weighted returns to this same strategy, and the value-weighted performance of strategies constructed from quintile sorts using name breaks (approximately equal number of firms in each portfolio) and market capitalization breaks (approximately equal total market capitalization in each portfolio), and using NYSE deciles. The average return is lowest for the quintile sort using cap breakpoints and value-weighted portfolios, and equals 28 bps/month with a t-statistics of 3.46. Out of the twenty-five alphas reported in Panel A, the t-statistics for twenty-five exceed two, and for fourteen exceed three.

Panel B reports for these same strategies the average monthly net returns and the generalized net alphas of [Novy-Marx and Velikov \(2016\)](#). These generalized alphas measure the extent to which a test asset improves the ex-post mean-variance efficient portfolio, accounting for the costs of trading both the asset and the explanatory fac-

tors. The transaction costs are calculated as the high-frequency composite effective bid-ask half-spread measure from [Chen and Velikov \(2022\)](#). The net average returns reported in the first column range between 24-31bps/month. The lowest return, (24 bps/month), is achieved from the quintile sort using cap breakpoints and value-weighted portfolios, and has an associated t-statistic of 3.00. Out of the twenty-five construction-methodology-factor-model pairs reported in Panel B, the CSUD trading strategy improves the achievable mean-variance efficient frontier spanned by the factor models in twenty-five cases, and significantly expands the achievable frontier in twenty-four cases.

Table 3 provides direct tests for the role size plays in the CSUD strategy performance. Panel A reports the average returns for the twenty-five portfolios constructed from a conditional double sort on size and CSUD, as well as average returns and alphas for long/short trading CSUD strategies within each size quintile. Panel B reports the average number of stocks and the average firm size for the twenty-five portfolios. Among the largest stocks (those with market capitalization greater than the 80th NYSE percentile), the CSUD strategy achieves an average return of 27 bps/month with a t-statistic of 2.80. Among these large cap stocks, the alphas for the CSUD strategy relative to the five most common factor models range from 22 to 28 bps/month with t-statistics between 2.27 and 2.87.

5 How does CSUD perform relative to the zoo?

Figure 2 puts the performance of CSUD in context, showing the long/short strategy performance relative to other strategies in the “factor zoo.” It shows Sharpe ratio histograms, both for gross and net returns (Panel A and B, respectively), for 212 documented anomalies in the zoo.¹ The vertical red line shows where the Sharpe ratio

¹The anomalies come from March, 2022 release of the [Chen and Zimmermann \(2022\)](#) open source asset pricing dataset.

for the CSUD strategy falls in the distribution. The CSUD strategy’s gross (net) Sharpe ratio of 0.51 (0.45) is greater than 93% (99%) of anomaly Sharpe ratios, respectively.

Figure 3 plots the growth of a \$1 invested in these same 212 anomaly trading strategies (gray lines), and compares those with the growth of a \$1 invested in the CSUD strategy (red line).² Ignoring trading costs, a \$1 invested in the CSUD strategy would have yielded \$6.73 which ranks the CSUD strategy in the top 3% across the 212 anomalies. Accounting for trading costs, a \$1 invested in the CSUD strategy would have yielded \$4.93 which ranks the CSUD strategy in the top 2% across the 212 anomalies.

Figure 4 plots percentile ranks for the 212 anomaly trading strategies in terms of gross and [Novy-Marx and Velikov \(2016\)](#) net generalized alphas with respect to the CAPM, and the Fama-French three-, four-, five-, and six-factor models from Table 1, and indicates the ranking of the CSUD relative to those. Panel A shows that the CSUD strategy gross alphas fall between the 64 and 69 percentiles across the five factor models. Panel B shows that, accounting for trading costs, a large fraction of anomalies have not improved the investment opportunity set of an investor with access to the factor models over the 196606 to 202306 sample. For example, 45% (53%) of the 212 anomalies would not have improved the investment opportunity set for an investor having access to the Fama-French three-factor (six-factor) model. The CSUD strategy has a positive net generalized alpha for five out of the five factor models. In these cases CSUD ranks between the 84 and 88 percentiles in terms of how much it could have expanded the achievable investment frontier.

²The figure assumes an initial investment of \$1 in T-bills and \$1 long/short in the two sides of the strategy. Returns are compounded each month, assuming, as in [Detzel et al. \(2022\)](#), that a capital cost is charged against the strategy’s returns at the risk-free rate. This excess return corresponds more closely to the strategy’s economic profitability.

6 Does CSUD add relative to related anomalies?

With so many anomalies, it is possible that any proposed, new cross-sectional predictor is just capturing some combination of known predictors. It is consequently natural to investigate to what extent the proposed predictor adds additional predictive power beyond the most closely related anomalies. Closely related anomalies are more likely to be formed on the basis of signals with higher absolute correlations. Figure 5 plots a name histogram of the correlations of CSUD with 210 filtered anomaly signals.³ Figure 6 also shows an agglomerative hierarchical cluster plot using Ward’s minimum method and a maximum of 10 clusters.

A closely related anomaly is also more likely to price CSUD or at least to weaken the power CSUD has predicting the cross-section of returns. Figure 7 plots histograms of t-statistics for predictability tests of CSUD conditioning on each of the 210 filtered anomaly signals one at a time. Panel A reports t-statistics on β_{CSUD} from Fama-MacBeth regressions of the form $r_{i,t} = \alpha + \beta_{CSUD}CSUD_{i,t} + \beta_X X_{i,t} + \epsilon_{i,t}$, where X stands for one of the 210 filtered anomaly signals at a time. Panel B plots t-statistics on α from spanning tests of the form: $r_{CSUD,t} = \alpha + \beta r_{X,t} + \epsilon_t$, where $r_{X,t}$ stands for the returns to one of the 210 filtered anomaly trading strategies at a time. The strategies employed in the spanning tests are constructed using quintile sorts, value-weighting, and NYSE breakpoints. Panel C plots t-statistics on the average returns to strategies constructed by conditional double sorts. In each month, we sort stocks into quintiles based one of the 210 filtered anomaly signals. Then, within each quintile, we sort stocks into quintiles based on CSUD. Stocks are finally grouped into five CSUD portfolios by combining stocks within each anomaly sorting portfolio. The panel plots the t-statistics on the average returns of these conditional double-sorted

³When performing tests at the underlying signal level (e.g., the correlations plotted in Figure 5), we filter the 212 anomalies to avoid small sample issues. For each anomaly, we calculate the common stock observations in an average month for which both the anomaly and the test signal are available. In the filtered anomaly set, we drop anomalies with fewer than 100 common stock observations in an average month.

CSUD trading strategies conditioned on each of the 210 filtered anomalies.

Table 4 reports Fama-MacBeth cross-sectional regressions of returns on CSUD and the six anomalies most closely-related to it. The six most-closely related anomalies are picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the R^2 from the spanning tests in Figure 7, Panel B. Controlling for each of these signals at a time, the t-statistics on the CSUD signal in these Fama-MacBeth regressions exceed 2.79, with the minimum t-statistic occurring when controlling for Net Payout Yield. Controlling for all six closely related anomalies, the t-statistic on CSUD is 1.71.

Similarly, Table 5 reports results from spanning tests that regress returns to the CSUD strategy onto the returns of the six most closely-related anomalies and the six Fama-French factors. Controlling for the six most-closely related anomalies individually, the CSUD strategy earns alphas that range from 16-21bps/month. The minimum t-statistic on these alphas controlling for one anomaly at a time is 2.03, which is achieved when controlling for Net Payout Yield. Controlling for all six closely-related anomalies and the six Fama-French factors simultaneously, the CSUD trading strategy achieves an alpha of 15bps/month with a t-statistic of 1.99.

7 Does CSUD add relative to the whole zoo?

Finally, we can ask how much adding CSUD to the entire factor zoo could improve investment performance. Figure 8 plots the growth of \$1 invested in trading strategies that combine multiple anomalies following Chen and Velikov (2022). The combinations use either the 155 anomalies from the zoo that satisfy our inclusion criteria (blue lines) or these 155 anomalies augmented with the CSUD signal.⁴ We consider

⁴We filter the 207 Chen and Zimmermann (2022) anomalies and require for each anomaly the average month to have at least 40% of the cross-sectional observations available for market capital-

one different methods for combining signals.

Panel A shows results using “Average rank” as the combination method. This method sorts stocks on the basis of forecast excess returns, where these are calculated on the basis of their average cross-sectional percentile rank across return predictors, and the predictors are all signed so that higher ranks are associated with higher average returns. For this method, \$1 investment in the 155-anomaly combination strategy grows to \$2333.55, while \$1 investment in the combination strategy that includes CSUD grows to \$2210.06.

8 Conclusion

This study provides compelling evidence for the significance of Capital Stock Utilization Delta (CSUD) as a valuable predictor of stock returns in the cross-section of equities. Our findings demonstrate that a value-weighted long/short trading strategy based on CSUD generates economically and statistically significant returns, with an impressive annualized Sharpe ratio of 0.51 (0.45) on a gross (net) basis. The strategy’s robustness is further validated by its persistent abnormal returns when controlling for traditional risk factors and related anomalies.

Particularly noteworthy is the strategy’s ability to maintain significant alpha even after accounting for transaction costs and controlling for the Fama-French five-factor model plus momentum, as well as six closely related anomalies from the factor zoo. The monthly alpha of 15 basis points (t-statistic = 1.99) in the presence of these controls suggests that CSUD captures unique information about future stock returns that is not fully explained by existing factors.

However, several limitations should be acknowledged. First, our analysis focuses on U.S. equity markets, and the signal’s effectiveness in international markets remains to be tested. Second, the study period may not fully capture the signal’s behavior

ization on CRSP in the period for which CSUD is available.

across different market regimes and economic cycles.

Future research could explore several promising directions. First, investigating the underlying economic mechanisms driving the CSUD premium would enhance our understanding of this anomaly. Second, examining potential interactions between CSUD and other established factors could reveal valuable insights for portfolio construction. Finally, testing the signal's effectiveness in different asset classes and international markets would help establish its broader applicability.

In conclusion, our findings suggest that CSUD represents a meaningful addition to the investment practitioner's toolkit, offering a robust signal for return prediction that survives rigorous statistical testing and remains significant after accounting for transaction costs.

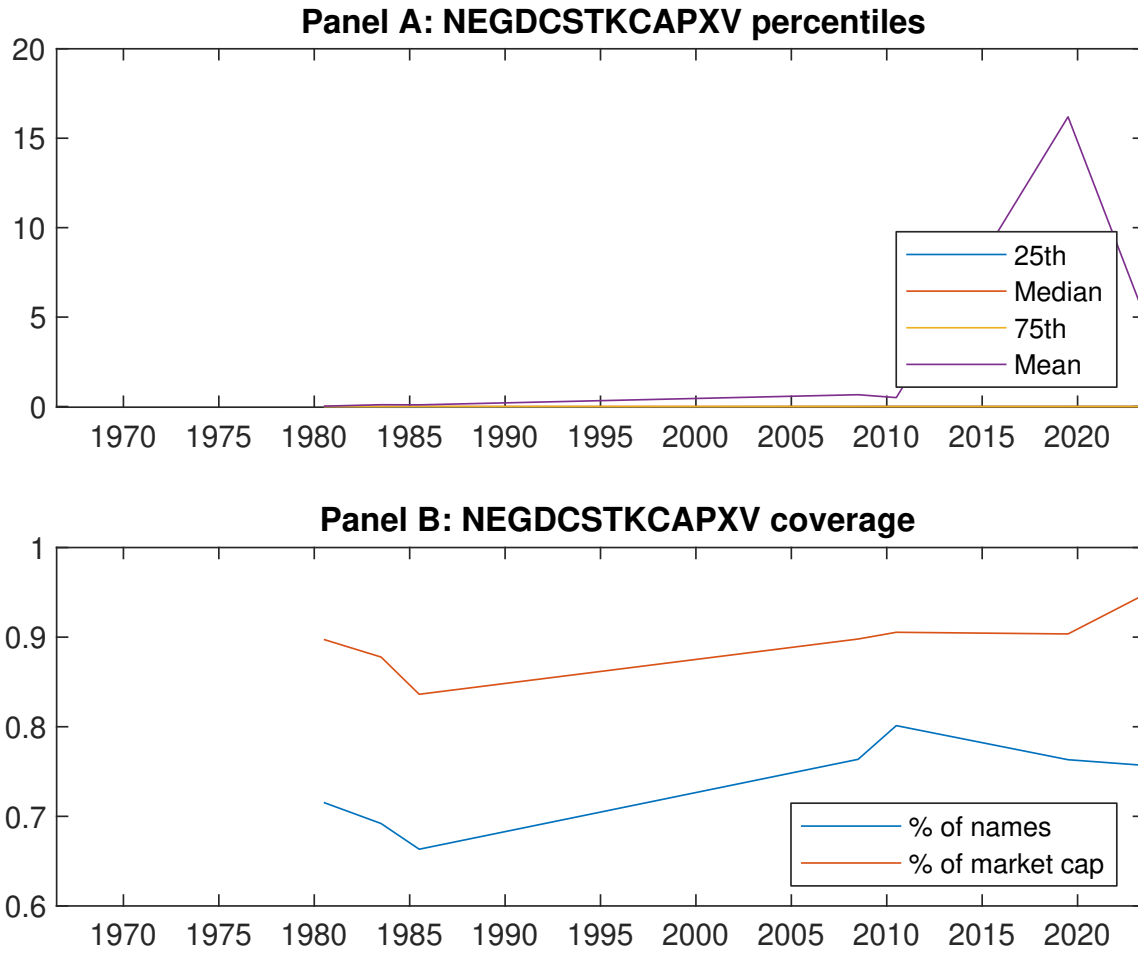

Figure 1: Times series of CSUD percentiles and coverage. This figure plots descriptive statistics for CSUD. Panel A shows cross-sectional percentiles of CSUD over the sample. Panel B plots the monthly coverage of CSUD relative to the universe of CRSP stocks with available market capitalizations.

Table 1: Basic sort: VW, quintile, NYSE-breaks

This table reports average excess returns and alphas for portfolios sorted on CSUD. At the end of each month, we sort stocks into five portfolios based on their signal using NYSE breakpoints. Panel A reports average value-weighted quintile portfolio (L,2,3,4,H) returns in excess of the risk-free rate, the long-short extreme quintile portfolio (H-L) return, and alphas with respect to the CAPM, Fama and French (1993) three-factor model, Fama and French (1993) three-factor model augmented with the Carhart (1997) momentum factor, Fama and French (2015) five-factor model, and the Fama and French (2015) five-factor model augmented with the Carhart (1997) momentum factor following Fama and French (2018). Panel B reports the factor loadings for the quintile portfolios and long-short extreme quintile portfolio in the Fama and French (2015) five-factor model. Panel C reports the average number of stocks and market capitalization of each portfolio. T-statistics are in brackets. The sample period is 196606 to 202306.

Table 2: Robustness to sorting methodology & trading costs

This table evaluates the robustness of the choices made in the CSUD strategy construction methodology. In each panel, the first row shows results from a quintile, value-weighted sort using NYSE break points as employed in Table 1. Each of the subsequent rows deviates in one of the three choices at a time, and the choices are specified in the first three columns. For each strategy construction methodology, the table reports average excess returns and alphas with respect to the CAPM, Fama and French (1993) three-factor model, Fama and French (1993) three-factor model augmented with the Carhart (1997) momentum factor, Fama and French (2015) five-factor model, and the Fama and French (2015) five-factor model augmented with the Carhart (1997) momentum factor following Fama and French (2018). Panel A reports average returns and alphas with no adjustment for trading costs. Panel B reports net average returns and Novy-Marx and Velikov (2016) generalized alphas as prescribed by Detzel et al. (2022). T-statistics are in brackets. The sample period is 196606 to 202306.

Panel A: Gross Returns and Alphas								
Portfolios	Breaks	Weights	r^e	α_{CAPM}	α_{FF3}	α_{FF4}	α_{FF5}	α_{FF6}
Quintile	NYSE	VW	0.31 [3.87]	0.34 [4.24]	0.30 [3.69]	0.26 [3.17]	0.21 [2.64]	0.19 [2.37]

Table 3: Conditional sort on size and CSUD

This table presents results for conditional double sorts on size and CSUD. In each month, stocks are first sorted into quintiles based on size using NYSE breakpoints. Then, within each size quintile, stocks are further sorted based on CSUD. Finally, they are grouped into twenty-five portfolios based on the intersection of the two sorts. Panel A presents the average returns to the 25 portfolios, as well as strategies that go long stocks with high CSUD and short stocks with low CSUD. Panel B documents the average number of firms and the average firm size for each portfolio. The sample period is 196606 to 202306.

Panel A: portfolio average returns and time-series regression results												
Size quintiles	CSUD Quintiles					CSUD Strategies

Figure 2: Distribution of Sharpe ratios.

This figure plots a histogram of Sharpe ratios for 212 anomalies, and compares the Sharpe ratio of the CSUD with them (red vertical line). Panel A plots results for gross Sharpe ratios. Panel B plots results for net Sharpe ratios.

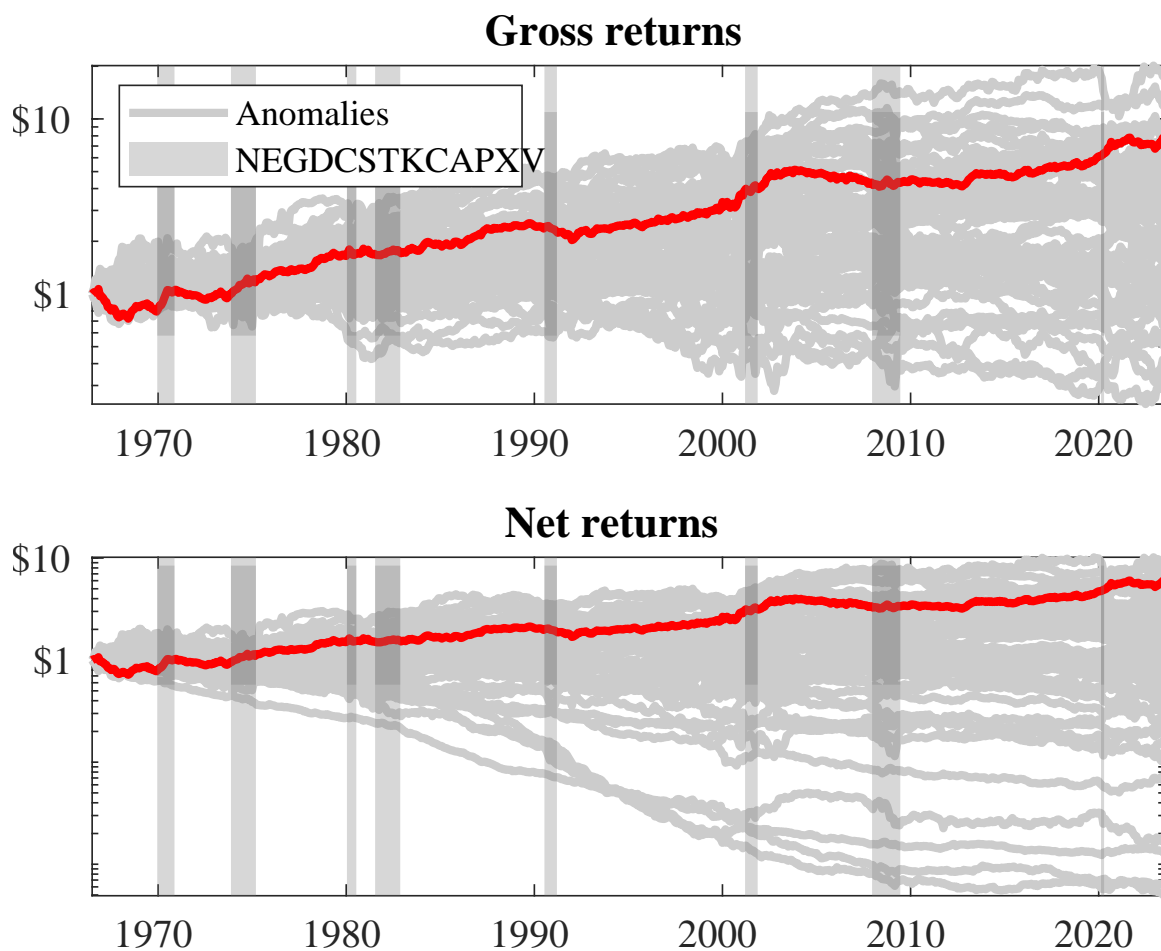

Figure 3: Dollar invested.

This figure plots the growth of a \$1 invested in 212 anomaly trading strategies (gray lines), and compares those with the CSUD trading strategy (red line). The strategies are constructed using value-weighted quintile sorts using NYSE breakpoints. Panel A plots results for gross strategy returns. Panel B plots results for net strategy returns.

Figure 4: Gross and generalized net alpha percentiles of anomalies relative to factor models

This figure plots the percentile ranks for 212 anomaly trading strategies in terms of alphas (solid lines), and compares those with the CSUD trading strategy alphas (diamonds). The strategies are constructed using value-weighted quintile sorts using NYSE breakpoints. The alphas include those with respect to the CAPM, Fama and French (1993) three-factor model, Fama and French (1993) three-factor model augmented with the Carhart (1997) momentum factor, Fama and French (2015) five-factor model, and the Fama and French (2015) five-factor model augmented with the Carhart (1997) momentum factor following Fama and French (2018). The left panel plots alphas with no adjustment for trading costs. The right panel plots Novy-Marx and Velikov (2016) net generalized alphas.

Figure 5: Distribution of correlations.

This figure plots a name histogram of correlations of 210 filtered anomaly signals with CSUD. The correlations are pooled. Panel A plots Pearson correlations, while Panel B plots Spearman rank correlations.

Figure 6: Agglomerative hierarchical cluster plot

This figure plots an agglomerative hierarchical cluster plot using Ward's minimum method and a maximum of 10 clusters.

Figure 7: Distribution of t-stats on conditioning strategies

This figure plots histograms of t-statistics for predictability tests of CSUD conditioning on each of the 210 filtered anomaly signals one at a time. Panel A reports t-statistics on β_{CSUD} from Fama-MacBeth regressions of the form $r_{i,t} = \alpha + \beta_{CSUD} CSUD_{i,t} + \beta_X X_{i,t} + \epsilon_{i,t}$, where X stands for one of the 210 filtered anomaly signals at a time. Panel B plots t-statistics on α from spanning tests of the form: $r_{CSUD,t} = \alpha + \beta r_{X,t} + \epsilon_t$, where $r_{X,t}$ stands for the returns to one of the 210 filtered anomaly trading strategies at a time. The strategies employed in the spanning tests are constructed using quintile sorts, value-weighting, and NYSE breakpoints. Panel C plots t-statistics on the average returns to strategies constructed by conditional double sorts. In each month, we sort stocks into quintiles based one of the 210 filtered anomaly signals at a time. Then, within each quintile, we sort stocks into quintiles based on CSUD. Stocks are finally grouped into five CSUD portfolios by combining stocks within each anomaly sorting portfolio. The panel plots the t-statistics on the average returns of these conditional double-sorted CSUD trading strategies conditioned on each of the 210 filtered anomalies.

Table 4: Fama-MacBeths controlling for most closely related anomalies

This table presents Fama-MacBeth results of returns on CSUD. and the six most closely related anomalies. The regressions take the following form: $r_{i,t} = \alpha + \beta_{CSUD}CSUD_{i,t} + \sum_{k=1}^s \beta_{X_k} X_{i,t}^k + \epsilon_{i,t}$. The six most closely related anomalies, X , are Share issuance (1 year), Net Payout Yield, Growth in book equity, Change in equity to assets, Share issuance (5 year), Asset growth. These anomalies were picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the R^2 from the spanning tests in Figure 7, Panel B. The sample period is 196606 to 202306.

Table 5: Spanning tests controlling for most closely related anomalies

This table presents spanning tests results of regressing returns to the CSUD trading strategy on trading strategies exploiting the six most closely related anomalies. The regressions take the following form: $r_t^{CSUD} = \alpha + \sum_{k=1}^6 \beta_{X_k} r_t^{X_k} + \sum_{j=1}^6 \beta_{f_j} r_t^{f_j} + \epsilon_t$, where X_k indicates each of the six most-closely related anomalies and f_j indicates the six factors from the [Fama and French \(2015\)](#) five-factor model augmented with the [Carhart \(1997\)](#) momentum factor. The six most closely related anomalies, X , are Share issuance (1 year), Net Payout Yield, Growth in book equity, Change in equity to assets, Share issuance (5 year), Asset growth. These anomalies were picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the R^2 from the spanning tests in Figure 7, Panel B. The sample period is 196606 to 202306.

Figure 8: Combination strategy performance

This figure plots the growth of a \$1 invested in trading strategies that combine multiple anomalies following [Chen and Velikov \(2022\)](#). In all panels, the blue solid lines indicate combination trading strategies that utilize 155 anomalies. The red solid lines indicate combination trading strategies that utilize the 155 anomalies as well as CSUD. Panel A shows results using "Average rank" as the combination method. See [Section 7](#) for details on the combination methods.
