

# Employees per Share Sensitivity and the Cross Section of Stock Returns

I. M. Harking

December 1, 2024

## Abstract

This paper studies the asset pricing implications of Employees per Share Sensitivity (EPSS), and its robustness in predicting returns in the cross-section of equities using the protocol proposed by [Novy-Marx and Velikov \(2023\)](#). A value-weighted long/short trading strategy based on EPSS achieves an annualized gross (net) Sharpe ratio of 0.64 (0.58), and monthly average abnormal gross (net) return relative to the [Fama and French \(2015\)](#) five-factor model plus a momentum factor of 23 (23) bps/month with a t-statistic of 2.97 (3.02), respectively. Its gross monthly alpha relative to these six factors plus the six most closely related strategies from the factor zoo (Share issuance (1 year), Growth in book equity, Net Payout Yield, Share issuance (5 year), Change in equity to assets, Asset growth) is 19 bps/month with a t-statistic of 2.58.

# 1 Introduction

The efficient market hypothesis suggests that stock prices should reflect all publicly available information. However, a growing body of literature documents various market anomalies that challenge this fundamental premise. While many of these anomalies are well-documented, the role of corporate employment decisions in asset pricing remains relatively unexplored. Understanding how firms’ employment choices affect stock returns is crucial, as labor represents one of the largest and most important factors of production.

Prior research has primarily focused on aggregate employment trends or industry-level workforce dynamics [Belo et al. \(2014\)](#); ?. Yet, the sensitivity of firm-level employment to equity issuance—a measure we term ‘Employees per Share Sensitivity’ (EPSS)—has received little attention despite its potential to reveal important information about management’s resource allocation decisions and future firm performance.

We propose that EPSS captures management’s strategic decisions about human capital investment relative to equity financing. When managers issue equity while simultaneously expanding their workforce, this may signal confidence in growth opportunities [Baker and Wurgler \(2002\)](#). Conversely, firms that reduce employment while issuing shares might be attempting to improve operational efficiency or responding to technological changes ?.

The theoretical foundation for EPSS’s predictive power builds on two established frameworks. First, the q-theory of investment ? suggests that firms optimally adjust their labor force in response to investment opportunities. Second, the market timing hypothesis ? posits that managers issue equity when they believe their shares are overvalued. The interaction between these two mechanisms suggests that EPSS could provide a unique signal about future returns.

Moreover, behavioral theories suggest that investors may systematically under-

react to complex signals that combine multiple corporate decisions [Hirshleifer et al. \(2009\)](#). The joint consideration of employment changes and share issuance requires sophisticated analysis of both operating and financing decisions, potentially leading to delayed price adjustment.

Our empirical analysis reveals that EPSS strongly predicts future stock returns. A value-weighted long-short portfolio strategy based on EPSS quintiles generates a significant monthly alpha of 23 basis points ( $t$ -statistic = 2.97) relative to the Fama-French six-factor model. The strategy achieves an impressive annualized Sharpe ratio of 0.64 before trading costs and 0.58 after accounting for transaction costs.

Importantly, the predictive power of EPSS persists across different size segments. Among the largest quintile of stocks, the strategy earns a monthly alpha of 22 basis points ( $t$ -statistic = 2.30), addressing concerns about implementability. The signal's robustness is further demonstrated by its performance after controlling for transaction costs, with net returns remaining economically and statistically significant.

The strategy's effectiveness extends beyond existing factors and anomalies. When controlling for the six most closely related anomalies and the Fama-French six factors simultaneously, EPSS continues to generate a significant monthly alpha of 19 basis points ( $t$ -statistic = 2.58). This persistence suggests that EPSS captures a unique dimension of expected returns not explained by known factors.

Our study makes several important contributions to the asset pricing literature. First, we introduce a novel predictor that bridges the gap between corporate finance and asset pricing by linking firms' employment decisions to equity issuance. This extends the work of [Belo et al. \(2014\)](#) on labor-based asset pricing factors and [Baker and Wurgler \(2002\)](#) on equity issuance timing.

Second, we demonstrate that EPSS provides incremental predictive power beyond existing anomalies. Our results remain robust after controlling for related signals such as asset growth [Cooper et al. \(2008\)](#), share issuance [Pontiff and Woodgate \(2008\)](#),

and investment ?. The signal’s effectiveness among large-cap stocks particularly distinguishes it from many other documented anomalies.

Finally, our findings have broader implications for understanding market efficiency and corporate decision-making. The persistent predictive power of EPSS suggests that markets do not fully incorporate the information content of firms’ joint employment and financing decisions, contributing to the growing literature on limited investor attention and processing capacity [Hirshleifer et al. \(2009\)](#).

## 2 Data

Our study investigates the predictive power of a financial signal derived from accounting data for cross-sectional returns, focusing specifically on Employees per Share Sensitivity. We obtain accounting and financial data from COMPUSTAT, covering firm-level observations for publicly traded companies. To construct our signal, we use COMPUSTAT’s item CSTK for common shares outstanding and item EMP for the total number of employees. The number of common shares outstanding (CSTK) represents the total number of shares issued by the company and currently held by shareholders, while the total number of employees (EMP) provides a measure of the firm’s workforce size. The construction of the signal follows a change-based approach, where we first calculate the year-over-year change in common shares outstanding ( $\text{CSTK} - \text{lag}(\text{CSTK})$ ) and then scale this change by the previous year’s number of employees ( $\text{lag}(\text{EMP})$ ). This ratio captures the relative change in share issuance or repurchase activity normalized by the firm’s workforce size, offering insight into how companies adjust their equity structure relative to their human capital base. By focusing on this relationship, the signal aims to reflect aspects of corporate financing decisions and labor intensity in a manner that is both scalable and interpretable. We construct this measure using end-of-fiscal-year values for both CSTK

and EMP to ensure consistency and comparability across firms and over time.

### 3 Signal diagnostics

Figure 1 plots descriptive statistics for the EPSS signal. Panel A plots the time-series of the mean, median, and interquartile range for EPSS. On average, the cross-sectional mean (median) EPSS is -1.54 (-0.00) over the 1966 to 2023 sample, where the starting date is determined by the availability of the input EPSS data. The signal’s interquartile range spans -0.41 to 0.00. Panel B of Figure 1 plots the time-series of the coverage of the EPSS signal for the CRSP universe. On average, the EPSS signal is available for 6.32% of CRSP names, which on average make up 7.83% of total market capitalization.

### 4 Does EPSS predict returns?

Table 1 reports the performance of portfolios constructed using a value-weighted, quintile sort on EPSS using NYSE breaks. The first two lines of Panel A report monthly average excess returns for each of the five portfolios and for the long/short portfolio that buys the high EPSS portfolio and sells the low EPSS portfolio. The rest of Panel A reports the portfolios’ monthly abnormal returns relative to the five most common factor models: the CAPM, the Fama and French (1993) three-factor model (FF3) and its variation that adds momentum (FF4), the Fama and French (2015) five-factor model (FF5), and its variation that adds momentum factor used in Fama and French (2018) (FF6). The table shows that the long/short EPSS strategy earns an average return of 0.37% per month with a t-statistic of 4.87. The annualized Sharpe ratio of the strategy is 0.64. The alphas range from 0.23% to 0.38% per month and have t-statistics exceeding 2.97 everywhere. The lowest alpha is with respect to the FF6 factor model.

Panel B reports the six portfolios’ loadings on the factors in the [Fama and French \(2018\)](#) six-factor model. The long/short strategy’s most significant loading is 0.32, with a t-statistic of 6.18 on the CMA factor. Panel C reports the average number of stocks in each portfolio, as well as the average market capitalization (in \$ millions) of the stocks they hold. In an average month, the five portfolios have at least 592 stocks and an average market capitalization of at least \$1,461 million.

Table 2 reports robustness results for alternative sorting methodologies, and accounting for transaction costs. These results are important, because many anomalies are far stronger among small cap stocks, but these small stocks are more expensive to trade. Construction methods, or even signal-size correlations, that over-weight small stocks can yield stronger paper performance without improving an investor’s achievable investment opportunity set. Panel A reports gross returns and alphas for the long/short strategies made using various different portfolio constructions. The first row reports the average returns and the alphas for the long/short strategy from Table 1, which is constructed from a quintile sort using NYSE breakpoints and value-weighted portfolios. The rest of the panel shows the equal-weighted returns to this same strategy, and the value-weighted performance of strategies constructed from quintile sorts using name breaks (approximately equal number of firms in each portfolio) and market capitalization breaks (approximately equal total market capitalization in each portfolio), and using NYSE deciles. The average return is lowest for the quintile sort using cap breakpoints and value-weighted portfolios, and equals 31 bps/month with a t-statistics of 3.96. Out of the twenty-five alphas reported in Panel A, the t-statistics for twenty-four exceed two, and for eighteen exceed three.

Panel B reports for these same strategies the average monthly net returns and the generalized net alphas of [Novy-Marx and Velikov \(2016\)](#). These generalized alphas measure the extent to which a test asset improves the ex-post mean-variance efficient portfolio, accounting for the costs of trading both the asset and the explanatory fac-

tors. The transaction costs are calculated as the high-frequency composite effective bid-ask half-spread measure from [Chen and Velikov \(2022\)](#). The net average returns reported in the first column range between 27-35bps/month. The lowest return, (27 bps/month), is achieved from the quintile sort using cap breakpoints and value-weighted portfolios, and has an associated t-statistic of 3.52. Out of the twenty-five construction-methodology-factor-model pairs reported in Panel B, the EPSS trading strategy improves the achievable mean-variance efficient frontier spanned by the factor models in twenty-five cases, and significantly expands the achievable frontier in twenty-four cases.

Table 3 provides direct tests for the role size plays in the EPSS strategy performance. Panel A reports the average returns for the twenty-five portfolios constructed from a conditional double sort on size and EPSS, as well as average returns and alphas for long/short trading EPSS strategies within each size quintile. Panel B reports the average number of stocks and the average firm size for the twenty-five portfolios. Among the largest stocks (those with market capitalization greater than the 80<sup>th</sup> NYSE percentile), the EPSS strategy achieves an average return of 28 bps/month with a t-statistic of 3.01. Among these large cap stocks, the alphas for the EPSS strategy relative to the five most common factor models range from 22 to 26 bps/month with t-statistics between 2.30 and 2.85.

## 5 How does EPSS perform relative to the zoo?

Figure 2 puts the performance of EPSS in context, showing the long/short strategy performance relative to other strategies in the “factor zoo.” It shows Sharpe ratio histograms, both for gross and net returns (Panel A and B, respectively), for 212 documented anomalies in the zoo.<sup>1</sup> The vertical red line shows where the Sharpe

---

<sup>1</sup>The anomalies come from March, 2022 release of the [Chen and Zimmermann \(2022\)](#) open source asset pricing dataset.

ratio for the EPSS strategy falls in the distribution. The EPSS strategy’s gross (net) Sharpe ratio of 0.64 (0.58) is greater than 97% (99%) of anomaly Sharpe ratios, respectively.

Figure 3 plots the growth of a \$1 invested in these same 212 anomaly trading strategies (gray lines), and compares those with the growth of a \$1 invested in the EPSS strategy (red line).<sup>2</sup> Ignoring trading costs, a \$1 invested in the EPSS strategy would have yielded \$10.44 which ranks the EPSS strategy in the top 1% across the 212 anomalies. Accounting for trading costs, a \$1 invested in the EPSS strategy would have yielded \$8.00 which ranks the EPSS strategy in the top 0% across the 212 anomalies.

Figure 4 plots percentile ranks for the 212 anomaly trading strategies in terms of gross and [Novy-Marx and Velikov \(2016\)](#) net generalized alphas with respect to the CAPM, and the Fama-French three-, four-, five-, and six-factor models from Table 1, and indicates the ranking of the EPSS relative to those. Panel A shows that the EPSS strategy gross alphas fall between the 69 and 76 percentiles across the five factor models. Panel B shows that, accounting for trading costs, a large fraction of anomalies have not improved the investment opportunity set of an investor with access to the factor models over the 196606 to 202306 sample. For example, 45% (53%) of the 212 anomalies would not have improved the investment opportunity set for an investor having access to the Fama-French three-factor (six-factor) model. The EPSS strategy has a positive net generalized alpha for five out of the five factor models. In these cases EPSS ranks between the 86 and 91 percentiles in terms of how much it could have expanded the achievable investment frontier.

---

<sup>2</sup>The figure assumes an initial investment of \$1 in T-bills and \$1 long/short in the two sides of the strategy. Returns are compounded each month, assuming, as in [Detzel et al. \(2022\)](#), that a capital cost is charged against the strategy’s returns at the risk-free rate. This excess return corresponds more closely to the strategy’s economic profitability.

## 6 Does EPSS add relative to related anomalies?

With so many anomalies, it is possible that any proposed, new cross-sectional predictor is just capturing some combination of known predictors. It is consequently natural to investigate to what extent the proposed predictor adds additional predictive power beyond the most closely related anomalies. Closely related anomalies are more likely to be formed on the basis of signals with higher absolute correlations. Figure 5 plots a name histogram of the correlations of EPSS with 210 filtered anomaly signals.<sup>3</sup> Figure 6 also shows an agglomerative hierarchical cluster plot using Ward's minimum method and a maximum of 10 clusters.

A closely related anomaly is also more likely to price EPSS or at least to weaken the power EPSS has predicting the cross-section of returns. Figure 7 plots histograms of t-statistics for predictability tests of EPSS conditioning on each of the 210 filtered anomaly signals one at a time. Panel A reports t-statistics on  $\beta_{EPSS}$  from Fama-MacBeth regressions of the form  $r_{i,t} = \alpha + \beta_{EPSS}EPSS_{i,t} + \beta_X X_{i,t} + \epsilon_{i,t}$ , where  $X$  stands for one of the 210 filtered anomaly signals at a time. Panel B plots t-statistics on  $\alpha$  from spanning tests of the form:  $r_{EPSS,t} = \alpha + \beta r_{X,t} + \epsilon_t$ , where  $r_{X,t}$  stands for the returns to one of the 210 filtered anomaly trading strategies at a time. The strategies employed in the spanning tests are constructed using quintile sorts, value-weighting, and NYSE breakpoints. Panel C plots t-statistics on the average returns to strategies constructed by conditional double sorts. In each month, we sort stocks into quintiles based one of the 210 filtered anomaly signals. Then, within each quintile, we sort stocks into quintiles based on EPSS. Stocks are finally grouped into five EPSS portfolios by combining stocks within each anomaly sorting portfolio. The panel plots the t-statistics on the average returns of these conditional double-sorted

---

<sup>3</sup>When performing tests at the underlying signal level (e.g., the correlations plotted in Figure 5), we filter the 212 anomalies to avoid small sample issues. For each anomaly, we calculate the common stock observations in an average month for which both the anomaly and the test signal are available. In the filtered anomaly set, we drop anomalies with fewer than 100 common stock observations in an average month.

EPSS trading strategies conditioned on each of the 210 filtered anomalies.

Table 4 reports Fama-MacBeth cross-sectional regressions of returns on EPSS and the six anomalies most closely-related to it. The six most-closely related anomalies are picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the  $R^2$  from the spanning tests in Figure 7, Panel B. Controlling for each of these signals at a time, the t-statistics on the EPSS signal in these Fama-MacBeth regressions exceed 2.98, with the minimum t-statistic occurring when controlling for Net Payout Yield. Controlling for all six closely related anomalies, the t-statistic on EPSS is 2.56.

Similarly, Table 5 reports results from spanning tests that regress returns to the EPSS strategy onto the returns of the six most closely-related anomalies and the six Fama-French factors. Controlling for the six most-closely related anomalies individually, the EPSS strategy earns alphas that range from 20-25bps/month. The minimum t-statistic on these alphas controlling for one anomaly at a time is 2.64, which is achieved when controlling for Net Payout Yield. Controlling for all six closely-related anomalies and the six Fama-French factors simultaneously, the EPSS trading strategy achieves an alpha of 19bps/month with a t-statistic of 2.58.

## 7 Does EPSS add relative to the whole zoo?

Finally, we can ask how much adding EPSS to the entire factor zoo could improve investment performance. Figure 8 plots the growth of \$1 invested in trading strategies that combine multiple anomalies following Chen and Velikov (2022). The combinations use either the 155 anomalies from the zoo that satisfy our inclusion criteria (blue lines) or these 155 anomalies augmented with the EPSS signal.<sup>4</sup> We consider one different methods for combining signals.

---

<sup>4</sup>We filter the 207 Chen and Zimmermann (2022) anomalies and require for each anomaly the average month to have at least 40% of the cross-sectional observations available for market capitalization on CRSP in the period for which EPSS is available.

Panel A shows results using “Average rank” as the combination method. This method sorts stocks on the basis of forecast excess returns, where these are calculated on the basis of their average cross-sectional percentile rank across return predictors, and the predictors are all signed so that higher ranks are associated with higher average returns. For this method, \$1 investment in the 155-anomaly combination strategy grows to \$2333.55, while \$1 investment in the combination strategy that includes EPSS grows to \$2470.31.

**Figure 1:** Times series of EPSS percentiles and coverage. This figure plots descriptive statistics for EPSS. Panel A shows cross-sectional percentiles of EPSS over the sample. Panel B plots the monthly coverage of EPSS relative to the universe of CRSP stocks with available market capitalizations.

**Table 1:** Basic sort: VW, quintile, NYSE-breaks

This table reports average excess returns and alphas for portfolios sorted on EPSS. At the end of each month, we sort stocks into five portfolios based on their signal using NYSE breakpoints. Panel A reports average value-weighted quintile portfolio (L,2,3,4,H) returns in excess of the risk-free rate, the long-short extreme quintile portfolio (H-L) return, and alphas with respect to the CAPM, Fama and French (1993) three-factor model, Fama and French (1993) three-factor model augmented with the Carhart (1997) momentum factor, Fama and French (2015) five-factor model, and the Fama and French (2015) five-factor model augmented with the Carhart (1997) momentum factor following Fama and French (2018). Panel B reports the factor loadings for the quintile portfolios and long-short extreme quintile portfolio in the Fama and French (2015) five-factor model. Panel C reports the average number of stocks and market capitalization of each portfolio. T-statistics are in brackets. The sample period is 196606 to 202306.

**Table 2:** Robustness to sorting methodology & trading costs

This table evaluates the robustness of the choices made in the EPSS strategy construction methodology. In each panel, the first row shows results from a quintile, value-weighted sort using NYSE break points as employed in Table 1. Each of the subsequent rows deviates in one of the three choices at a time, and the choices are specified in the first three columns. For each strategy construction methodology, the table reports average excess returns and alphas with respect to the CAPM, Fama and French (1993) three-factor model, Fama and French (1993) three-factor model augmented with the Carhart (1997) momentum factor, Fama and French (2015) five-factor model, and the Fama and French (2015) five-factor model augmented with the Carhart (1997) momentum factor following Fama and French (2018). Panel A reports average returns and alphas with no adjustment for trading costs. Panel B reports net average returns and Novy-Marx and Velikov (2016) generalized alphas as prescribed by Detzel et al. (2022). T-statistics are in brackets. The sample period is 196606 to 202306.

Panel A: Gross Returns and Alphas								
Portfolios	Breaks	Weights	$r^e$	$\alpha_{\text{CAPM}}$	$\alpha_{\text{FF3}}$	$\alpha_{\text{FF4}}$	$\alpha_{\text{FF5}}$	$\alpha_{\text{FF6}}$
Quintile	NYSE	VW	0.37 [4.87]	0.38 [4.99]	0.35 [4.56]	0.32 [4.05]	0.25 [3.22]	0.23 [2.97]

**Table 3:** Conditional sort on size and EPSS

This table presents results for conditional double sorts on size and EPSS. In each month, stocks are first sorted into quintiles based on size using NYSE breakpoints. Then, within each size quintile, stocks are further sorted based on EPSS. Finally, they are grouped into twenty-five portfolios based on the intersection of the two sorts. Panel A presents the average returns to the 25 portfolios, as well as strategies that go long stocks with high EPSS and short stocks with low EPSS. Panel B documents the average number of firms and the average firm size for each portfolio. The sample period is 196606 to 202306.

Panel A: portfolio average returns and time-series regression results												
Size quintiles	EPSS Quintiles					EPSS Strategies						
		(L)	(2)	(3)	(4)	(H)	$r^e$	$\alpha_{CAPM}$	$\alpha_{FF3}$	$\alpha_{FF4}$	$\alpha_{FF5}$	$\alpha_{FF6}$
	(1)	0.40	0.66	0.87	0.95	0.97	0.57	0.63	0.57	0.51	0.38	0.35

**Figure 2:** Distribution of Sharpe ratios.

This figure plots a histogram of Sharpe ratios for 212 anomalies, and compares the Sharpe ratio of the EPSS with them (red vertical line). Panel A plots results for gross Sharpe ratios. Panel B plots results for net Sharpe ratios.

**Figure 3:** Dollar invested.

This figure plots the growth of a \$1 invested in 212 anomaly trading strategies (gray lines), and compares those with the EPSS trading strategy (red line). The strategies are constructed using value-weighted quintile sorts using NYSE breakpoints. Panel A plots results for gross strategy returns. Panel B plots results for net strategy returns.

**Figure 4:** Gross and generalized net alpha percentiles of anomalies relative to factor models

This figure plots the percentile ranks for 212 anomaly trading strategies in terms of alphas (solid lines), and compares those with the EPSS trading strategy alphas (diamonds). The strategies are constructed using value-weighted quintile sorts using NYSE breakpoints. The alphas include those with respect to the CAPM, [Fama and French \(1993\)](#) three-factor model, [Fama and French \(1993\)](#) three-factor model augmented with the [Carhart \(1997\)](#) momentum factor, [Fama and French \(2015\)](#) five-factor model, and the [Fama and French \(2015\)](#) five-factor model augmented with the [Carhart \(1997\)](#) momentum factor following [Fama and French \(2018\)](#). The left panel plots alphas with no adjustment for trading costs. The right panel plots [Novy-Marx and Velikov \(2016\)](#) net generalized alphas.

**Figure 5:** Distribution of correlations.  
This figure plots a name histogram of correlations of 210 filtered anomaly signals with EPSS. The correlations are pooled. Panel A plots Pearson correlations, while Panel B plots Spearman rank correlations.

This figure plots an agglomerative hierarchical cluster plot using Ward's minimum method and a maximum of 10 clusters.

**Figure 7:** Distribution of t-stats on conditioning strategies

This figure plots histograms of t-statistics for predictability tests of EPSS conditioning on each of the 210 filtered anomaly signals one at a time. Panel A reports t-statistics on  $\beta_{EPSS}$  from Fama-MacBeth regressions of the form  $r_{i,t} = \alpha + \beta_{EPSS} EPSS_{i,t} + \beta_X X_{i,t} + \epsilon_{i,t}$ , where  $X$  stands for one of the 210 filtered anomaly signals at a time. Panel B plots t-statistics on  $\alpha$  from spanning tests of the form:  $r_{EPSS,t} = \alpha + \beta r_{X,t} + \epsilon_t$ , where  $r_{X,t}$  stands for the returns to one of the 210 filtered anomaly trading strategies at a time. The strategies employed in the spanning tests are constructed using quintile sorts, value-weighting, and NYSE breakpoints. Panel C plots t-statistics on the average returns to strategies constructed by conditional double sorts. In each month, we sort stocks into quintiles based on one of the 210 filtered anomaly signals at a time. Then, within each quintile, we sort stocks into quintiles based on EPSS. Stocks are finally grouped into five EPSS portfolios by combining stocks within each anomaly sorting portfolio. The panel plots the t-statistics on the average returns of these conditional double-sorted EPSS trading strategies conditioned on each of the 210 filtered anomalies.

**Table 4:** Fama-MacBeths controlling for most closely related anomalies

This table presents Fama-MacBeth results of returns on EPSS. and the six most closely related anomalies. The regressions take the following form:  $r_{i,t} = \alpha + \beta_{EPSS}EPSS_{i,t} + \sum_{k=1}^s \beta_{X_k}X_{i,t}^k + \epsilon_{i,t}$ . The six most closely related anomalies,  $X$ , are Share issuance (1 year), Growth in book equity, Net Payout Yield, Share issuance (5 year), Change in equity to assets, Asset growth. These anomalies were picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the  $R^2$  from the spanning tests in Figure 7, Panel B. The sample period is 196606 to 202306.

**Table 5:** Spanning tests controlling for most closely related anomalies

This table presents spanning tests results of regressing returns to the EPSS trading strategy on trading strategies exploiting the six most closely related anomalies. The regressions take the following form:  $r_t^{EPSS} = \alpha + \sum_{k=1}^6 \beta_{X_k} r_t^{X_k} + \sum_{j=1}^6 \beta_{f_j} r_t^{f_j} + \epsilon_t$ , where  $X_k$  indicates each of the six most-closely related anomalies and  $f_j$  indicates the six factors from the [Fama and French \(2015\)](#) five-factor model augmented with the [Carhart \(1997\)](#) momentum factor. The six most closely related anomalies,  $X$ , are Share issuance (1 year), Growth in book equity, Net Payout Yield, Share issuance (5 year), Change in equity to assets, Asset growth. These anomalies were picked as those with the highest combined rank where the ranks are based on the absolute value of the Spearman correlations in Panel B of Figure 5 and the  $R^2$  from the spanning tests in Figure 7, Panel B. The sample period is 196606 to 202306.

**Figure 8:** Combination strategy performance

This figure plots the growth of a \$1 invested in trading strategies that combine multiple anomalies following [Chen and Velikov \(2022\)](#). In all panels, the blue solid lines indicate combination trading strategies that utilize 155 anomalies. The red solid lines indicate combination trading strategies that utilize the 155 anomalies as well as EPSS. Panel A shows results using "Average rank" as the combination method. See [Section 7](#) for details on the combination methods.
